TRICYCLIC INHIBITORS OF POLY(ADP-RIBOSE) POLYMERASES

This application claims priority from Provisional Application No. 60/115,431 filed January 11, 1999, which is incorporated herein by reference in its entirety.

5

FIELD OF THE INVENTION

The invention pertains to compounds that inhibit poly(ADP-ribose) polymerases, thereby retarding the repair of damage to DNA strands, and to methods of preparing such compounds. The invention also relates the use of such compounds in pharmaceutical compositions and therapeutic treatments useful for potentiation of anti-cancer therapies and inhibition of neurotoxicity consequent to stroke, head trauma, and neurodegenerative diseases.

10

BACKGROUND OF THE INVENTION

Poly(ADP-ribose) polymerases (PARPs), nuclear enzymes found in almost all eukaryotic cells, catalyze the transfer of ADP-ribose units from nicotinamide adenine dinucleotide (NAD⁺) to nuclear acceptor proteins, and are responsible for the formation of protein-bound linear and branched homo-ADP-ribose polymers. Activation of PARP and resultant formation of poly(ADP-ribose) can be induced by DNA strand breaks after exposure to chemotherapy, ionizing radiation, oxygen free radicals, or nitric oxide (NO).

15

20

Because this cellular ADP-ribose transfer process is associated with the repair of DNA strand breakage in response to DNA damage caused by radiotherapy or chemotherapy, it can contribute to the resistance that often develops to various types of cancer therapies. Consequently, inhibition of PARP may retard intracellular DNA repair and enhance the antitumor effects of cancer therapy. Indeed, *in vitro* and *in vivo* data show that many PARP inhibitors potentiate the effects of ionizing radiation or cytotoxic drugs such as DNA methylating agents. Therefore, inhibitors of the PARP enzyme are useful as cancer chemotherapeutics.

25

In addition, it has been shown that inhibition of PARP promotes resistance to brain injury after stroke (Endres et al., "Ischemic Brain Injury is Mediated by the

30

Activation of Poly(ADP-Ribose)Polymerase," *J. Cerebral Blood Flow Metab.*

17:1143-1151 (1997); Zhang, "PARP Inhibition Results in Substantial

Neuroprotection in Cerebral Ischemia," *Cambridge Healthtech Institute's Conference on Acute Neuronal Injury: New Therapeutic Opportunities*. Sept. 18-24, 1998, Las

5 Vegas, Nevada). The activation of PARP by DNA damage is believed to play a role in the cell death consequent to stroke, head trauma, and neurodegenerative diseases.

DNA is damaged by excessive amounts of NO produced when the NO synthase enzyme is activated as a result of a series of events initiated by the release of the

10 neurotransmitter glutamate from depolarized nerve terminals (Cosi et al., "Poly(ADP-Ribose) Polymerase Revisited: A New Role for an Old Enzyme: PARP Involvement in Neurodegeneration and PARP Inhibitors as Possible Neuroprotective Agents,"

Ann. N.Y. Acad. Sci., 366-379). Cell death is believed to occur as a result of energy depletion as NAD⁺ is consumed by the enzyme-catalyzed PARP reaction. Therefore, inhibitors of the PARP enzyme are useful inhibitors of neurotoxicity consequent to

15 stroke, head trauma, and neurodegenerative diseases.

Further, inhibition of PARP should be a useful approach for treatment of conditions or diseases associated with cellular senescence, such as skin aging, through the role of PARP in the signaling of DNA damage. See, e.g., U.S. Patent No. 5,589,483, which describes a method to extend the lifespan and proliferative capacity

20 of cells comprising administering a therapeutically effective amount of a PARP inhibitor to the cells under conditions such that PARP activity is inhibited. Hence, inhibitors of the PARP enzyme are useful therapeutics for skin aging.

In yet a further application, PARP inhibition is being explored at the clinical level to prevent development of insulin-dependent diabetes mellitus in susceptible

25 individuals (Saldeen et al., "Nicotinamide-induced apoptosis in insulin producing cells in associated with cleavage of poly(ADP-ribose) polymerase," *Mol. Cellular Endocrinol.* (1998), 139:99-107). PARP inhibitors should therefore be useful as diabetes-prevention therapeutics.

PARP inhibition is also an approach for treating inflammatory conditions such

30 as arthritis (Szabo et al., "Protective effect of an inhibitor of poly(ADP-ribose)

synthetase in collagen-induced arthritis," *Portland Press Proc.* (1998), 15:280-281; Szabo, "Role of Poly(ADP-ribose) Synthetase in Inflammation," *Eur. J. Biochem.* (1998), 350(1):1-19; Szabo et al., "Protection Against Peroxynitrite-induced Fibroblast Injury and Arthritis Development by Inhibition of Poly(ADP-ribose) Synthetase," *Proc. Natl. Acad. Sci. USA* (1998), 95(7):3867-72). PARP inhibitors are therefore useful as therapeutics for inflammatory conditions.

Inhibition of PARP has usefulness for protection against myocardial ischemia and reperfusion injury (Zingarelli et al., "Protection against myocardial ischemia and reperfusion injury by 3-aminobenzamide, an inhibitor of poly (ADP-ribose) synthetase," *Cardiovascular Research* (1997), 36:205-215). Therefore, PARP inhibitors are useful in therapy of cardiovascular diseases.

The PARP family of enzymes is extensive. It has recently been shown that tankyrases, which bind to the telomeric protein TRF-1, a negative regulator of telomere length maintenance, have a catalytic domain that is strikingly homologous to PARP and have been shown to have PARP activity *in vitro*. It has been proposed that telomere function in human cells is regulated by poly(ADP-ribosyl)ation. PARP inhibitors have utility as tools to study this function. Further, as a consequence of regulation of telomerase activity by tankyrase, PARP inhibitors should have utility as agents for regulation of cell life-span, e.g., for use in cancer therapy to shorten the life-span of immortal tumor cells, or as anti-aging therapeutics, since telomere length is believed to be associated with cell senescence.

Competitive inhibitors of PARP are known. For example, Banasik et al. ("Specific Inhibitors of Poly(ADP-Ribose) Synthetase and Mono(ADP-Ribosyl)transferase," *J. Biol. Chem.* (1992) 267: 1569-1575) examined the PARP-inhibiting activity of 132 compounds, the most potent of which were 4-amino-1,8-naphthalimide, 6(5*H*)-phenanthridone, 2-nitro-6(5*H*)-phenanthridone, and 1,5-dihydroxyisoquinoline. Griffin et al. reported the PARP-inhibiting activity for a series of benzamide compounds (U.S. Patent No. 5,756,510; see also "Novel Potent Inhibitors of the DNA Repair Enzyme poly (ADP-ribose)polymerase (PARP)," *Anti-Cancer Drug Design* (1995), 10:507-514) and quinalozinone compounds

(International Publication No. WO 98/33802). Suto et al. reported PARP inhibition by a series of dihydroisoquinoline compounds ("Dihydroisoquinolines: The Design and Synthesis of a New Series of Potent Inhibitors of Poly(ADP-ribose) Polymerase," *Anti-Cancer Drug Design* (1991), 7:107-117). Griffin et al. have reported other

5 PARP inhibitors of the quinazoline class ("Resistance-Modifying Agents. 5. Synthesis and Biological Properties of Quinazoline Inhibitors of the DNA Repair Enzyme Poly(ADP-ribose) Polymerase (PARP)," *J. Med. Chem.*, ASAP Article 10.1021/jm980273t S0022-2623(98)00273-8; Web Release Date: December 1, 1998).

Nonetheless, there is still a need for small-molecule compounds that are

10 potent PARP inhibitors, especially those that have physical and chemical properties desirable for pharmaceutical applications.

30 to an intermediate 3-substituted-4-carboalkoxy indole, thereby incorporating the

intended ring carbon atoms, terminally substituted with one nitrogen atom, usually in the form of a nitro group. Additional functional groups, such as formyl or acyl, may be incorporated at the 3-position in this step. The nitro group is reduced to an amine and cyclized upon the 4-carboalkoxy group in an amide-forming reaction to yield the tricyclic heterocycle. The synthetic methods may further comprise derivatization at N-1 and C-2. The 3-formyl or 3-acyl intermediates can be converted to nitrogen-containing intermediates or to tricyclic indoles with N-N bonds, such as the compounds of formula (III).

DETAILED DESCRIPTION OF THE INVENTION AND PREFERRED EMBODIMENTS

In accordance with a convention used in the art, the symbol  is used in structural formulas herein to depict the bond that is the point of attachment of the moiety or substituent to the core or backbone structure. In accordance with another convention, in some structural formulae herein the carbon atoms and their bound

20 hydrogen atoms are not explicitly depicted, e.g.,  represents a methyl group,

 represents an ethyl group,  represents a cyclopentyl group, etc.

As used herein, the term "alkyl" means a branched- or straight-chained (linear) paraffinic hydrocarbon group (saturated aliphatic group) having from 1 to 10 carbon atoms in its chain, which may be generally represented by the formula

25 C_kH_{2k+1} , where k is an integer of from 1 to 10. Examples of alkyl groups include

methyl, ethyl, n-propyl, isopropyl, n-butyl, isobutyl, t-butyl, pentyl, n-pentyl, isopentyl, neopentyl, and hexyl, and the simple aliphatic isomers thereof. A "lower alkyl" is intended to mean an alkyl group having from 1 to 4 carbon atoms in its chain.

5 The term "alkenyl" means a branched- or straight-chained olefinic hydrocarbon group (unsaturated aliphatic group having one or more double bonds) containing 2 to 10 carbons in its chain. Exemplary alkenyls include ethenyl, 1-propenyl, 2-propenyl, 1-butenyl, 2-butenyl, isobutenyl, and the various isomeric pentenyls and hexenyls (including both cis and trans isomers).

 The term "carbocycle" refers to a saturated, partially saturated, unsaturated, or
15 aromatic, monocyclic or fused or non-fused polycyclic, ring structure having only carbon ring atoms (no heteroatoms, i.e., non-carbon ring atoms). Exemplary carbocycles include cycloalkyl, aryl, and cycloalkyl-aryl groups.

The term "optionally substituted" is intended to indicate that the specified group is unsubstituted or substituted by one or more suitable substituents, unless the
15 optional substituents are expressly specified, in which case the term indicates that the group is unsubstituted or substituted with the specified substituents. Unless indicated otherwise (e.g., by indicating that a specified group is unsubstituted), the various groups defined above may be generally unsubstituted or substituted (i.e., they are optionally substituted) with one or more suitable substituents.

The term "substituent" or "suitable substituent" is intended to mean any substituent for a group that may be recognized or readily selected by the artisan, such as through routine testing, as being pharmaceutically suitable. Pharmaceutical Methods and Compositions:

The invention is also directed to a method of inhibiting PARP enzyme activity, comprising contacting the enzyme with an effective amount of a compound of formula (I), or a pharmaceutically acceptable salt, prodrug, active metabolite, or solvate thereof. For example, PARP activity may be inhibited in mammalian tissue by administering a compound of formula (I) or a pharmaceutically acceptable salt, prodrug, active metabolite, or solvate thereof. In addition to the compounds specified above, the following known compounds have been found to be useful for inhibiting PARP enzyme activity:

"Treating" or "treatment" is intended to mean mitigating or alleviating an injury or a disease condition in a mammal, such as a human, that is mediated by the inhibition of PARP activity, such as by potentiation of anti-cancer therapies or inhibition of neurotoxicity consequent to stroke, head trauma, and neurodegenerative diseases. Types of treatment include: (a) as a prophylactic use in a mammal, particularly when the mammal is found to be predisposed to having the disease condition but not yet diagnosed as having it; (b) inhibition of the disease condition; and/or (c) alleviation, in whole or in part, of the disease condition.

One treatment method involves improving the effectiveness of a cytotoxic drug or radiotherapy administered to a mammal in the course of therapeutic

treatment, comprising administering to the mammal an effective amount of an agent (compound, pharmaceutically acceptable salt, prodrug, active metabolite, or solvate) in conjunction with administration of the cytotoxic drug (e.g., topotecan or irinotecan) or radiotherapy. The PARP-inhibiting agents may also be advantageously used in a method for reducing neurotoxicity consequent to stroke, head trauma, and neurodegenerative diseases in a mammal by administering a therapeutically effective amount of an inventive agent to the mammal. The PARP-inhibiting agents of the invention may also be used in a method for delaying the onset of cell senescence associated with skin aging in a human, comprising administering to fibroblast cells in the human an effective PARP-inhibiting amount of an agent. Further, the agents may also be used in a method for helping prevent the development of insulin-dependent diabetes mellitus in a susceptible individual, comprising administering a therapeutically effective amount of an agent. Additionally, the agents may also be employed in a method for treating an inflammatory condition in a mammal, comprising administering a therapeutically effective amount of an agent to the mammal. Moreover, the agents may also be used in a method for treating cardiovascular disease in a mammal, comprising administering to the mammal a therapeutically effective amount of a PARP-inhibiting agent. As knowledge regarding the therapeutic roles of PARP inhibitors progresses in the art, other utilities of the PARP-inhibiting agents of the invention will become apparent.

The activity of the inventive compounds as inhibitors of PARP activity may be measured by any of the suitable methods known or available in the art, including by *in vivo* and *in vitro* assays. An example of a suitable assay for activity measurements is the PARP enzyme inhibition assay described herein.

Administration of the compounds of the formula (I) and their pharmaceutically acceptable prodrugs, salts, active metabolites, and solvates may be performed according to any of the accepted modes of administration available in the art. Illustrative examples of suitable modes of administration include oral, nasal, parenteral, topical, transdermal, and rectal delivery. Oral and intravenous delivery are preferred.

An inventive compound of formula (I) or a pharmaceutically acceptable salt, prodrug, active metabolite, or solvate thereof may be administered as a pharmaceutical composition in any pharmaceutical form recognizable to the skilled artisan as being suitable. Suitable pharmaceutical forms include solid, semisolid, liquid, or lyophilized formulations, such as tablets, powders, capsules, suppositories, suspensions, liposomes, and aerosols. Pharmaceutical compositions of the invention may also include suitable excipients, diluents, vehicles, and carriers, as well as other pharmaceutically active agents (including other PARP-inhibiting agents), depending upon the intended use.

Acceptable methods of preparing suitable pharmaceutical forms of the pharmaceutical compositions are known or may be routinely determined by those skilled in the art. For example, pharmaceutical preparations may be prepared following conventional techniques of the pharmaceutical chemist involving steps such as mixing, granulating, and compressing when necessary for tablet forms, or mixing, filling, and dissolving the ingredients as appropriate to give the desired products for oral, parenteral, topical, intravaginal, intranasal, intrabronchial, intraocular, intraaural, and/or rectal administration.

Solid or liquid pharmaceutically acceptable carriers, diluents, vehicles, or excipients may be employed in the pharmaceutical compositions. Illustrative solid carriers include starch, lactose, calcium sulphate dihydrate, terra alba, sucrose, talc, gelatin, pectin, acacia, magnesium stearate, and stearic acid. Illustrative liquid carriers include syrup, peanut oil, olive oil, saline solution, and water. The carrier or diluent may include a suitable prolonged-release material, such as glyceryl monostearate or glyceryl distearate, alone or with a wax. When a liquid carrier is used, the preparation may be in the form of a syrup, elixir, emulsion, soft gelatin capsule, sterile injectable liquid (e.g., solution), or a nonaqueous or aqueous liquid suspension.

A dose of the pharmaceutical composition contains at least a therapeutically effective amount of a PARP-inhibiting agent (i.e., a compound of formula (I), (II), or (III), or a pharmaceutically acceptable salt, prodrug, active metabolite, or solvate

thereof), and preferably contains one or more pharmaceutical dosage units. The selected dose may be administered to a mammal, for example, a human patient, in need of treatment of a condition mediated by inhibition of PARP activity, by any known or suitable method of administering the dose, including: topically, for example, as an ointment or cream; orally; rectally, for example, as a suppository; parenterally by injection; or continuously by intravaginal, intranasal, intrabronchial, intraaural, or intraocular infusion. A "therapeutically effective amount" is intended to mean the amount of an agent that, when administered to a mammal in need thereof, is sufficient to effect treatment for injury or disease condition mediated by inhibition of PARP activity, such as for potentiation of anti-cancer therapies and inhibition of neurotoxicity consequent to stroke, head trauma, and neurodegenerative diseases. The amount of a given compound of the invention that will be therapeutically effective will vary depending upon factors such as the particular compound, the disease condition and the severity thereof, the identity of the mammal in need thereof, which amount may be routinely determined by artisans.

It will be appreciated that the actual dosages of the PARP-inhibiting agents used in the pharmaceutical compositions of this invention will be selected according to the particular complex being used, the particular composition formulated, the mode of administration and the particular site, and the host and condition being treated. Optimal dosages for a given set of conditions can be ascertained by those skilled in the art using conventional dosage-determination tests. For oral administration, e.g., a dose that may be employed is from about 0.001 to about 1000 mg/kg body weight, with courses of treatment repeated at appropriate intervals.

Synthetic Processes:

The present invention is further directed to methods of synthesizing the PARP-inhibiting agents by processes such as those set forth below for exemplary compounds of the invention. In the following examples, the structures of the compounds were confirmed by one or more of the following: proton magnetic resonance spectroscopy, infrared spectroscopy, elemental microanalysis, mass

spectrometry, thin layer chromatography, high performance liquid chromatography, and melting point.

Proton magnetic resonance (^1H NMR) spectra were determined using a 300 megahertz Tech-Mag, Bruker Avance 300DPX, or Bruker Avance 500 DRX spectrometer operating at a field strength of 300 or 500 megahertz (MHz). Chemical shifts are reported in parts per million (ppm, δ) downfield from an internal tetramethylsilane standard. Alternatively, ^1H NMR spectra were referenced to residual protic solvent signals as follows: $\text{CHCl}_3 = 7.26$ ppm; DMSO = 2.49 ppm; $\text{C}_6\text{HD}_5 = 7.15$ ppm. Peak multiplicities are designated as follows: s = singlet; d = doublet; dd = doublet of doublets; t = triplet; q = quartet; br = broad resonance; and m = multiplet. Coupling constants are given in Hertz (Hz). Infrared absorption (IR) spectra were obtained using a Perkin-Elmer 1600 series or a Midac Corporation FTIR spectrometer. Elemental microanalyses were performed by Atlantic Microlab Inc. (Norcross, GA) or Galbraith Laboratories (Nashville, TN), and gave results for the elements stated within $\pm 0.4\%$ of the theoretical values. Flash column chromatography was performed using Silica gel 60 (Merck Art 9385). Analytical thin layer chromatography (TLC) was performed using precoated sheets of Silica 60 F254 (Merck Art 5719). Melting points (mp) were determined on a MelTemp apparatus and are uncorrected. All reactions were performed in septum-sealed flasks under a slight positive pressure of argon, unless otherwise noted. All commercial solvents were reagent-grade or better and used as supplied.

The following abbreviations may be used herein: Et_2O (diethyl ether); DMF (*N,N*-dimethylformamide); DMSO (dimethylsulfoxide); MeOH (methanol); EtOH (ethanol); EtOAc (ethyl acetate); THF (tetrahydrofuran); Ac (acetyl); Me (methyl); Et (ethyl); and Ph (phenyl).

The general reaction protocols described below may be used to prepare the compounds of the invention.

General Synthetic Scheme 1:

- In Scheme 1, 4-carbomethoxyindole **A** is formylated or acylated under various
- 5 Vilsmeier or Friedel-Crafts conditions to yield **B**, where R^{23} is CHO or COR^{24} . 4-Carbomethoxyindole **A** serves as substrate for a 1,4-addition reaction to yield the nitroethyl intermediate **B**, where R^{23} is $\text{CHR}^{25}\text{CH}_2\text{NO}_2$. Intermediate **B**, where R^{23} is CHO, is transformed to the corresponding oxime (R^{27} is CH=NOH) or nitroalkene

(R^{27} is $CH=CHNO_2$) **C**, which is then catalytically reduced to the aminoalkyl derivative **D**. Nitroethyl intermediate **B** is transformed directly to **D** (when R^{23} is $CHR^{25}CH_2NO_2$) by reduction in some cases. Compound **D** spontaneously cyclizes to tricyclic lactams **E** ($n = 2$) and **EE**. Exposure of intermediate **D** to basic conditions also leads to tricyclic lactams **E** and **EE**. Compound **E** is optionally N-alkylated to form N-alkylated **E** or halogenated to yield **F**. Intermediate **F** can be transformed via a metal-catalyzed reaction (typically with palladium as catalyst) into a number of different substituted tricyclic lactams **G**, where R^{29} is aryl, alkyl, alkenyl or alkynyl. **G** is optionally further modified at R^{22} , R^{29} and R^{30} .

10 Acyl-substituted compounds of formula **J** (e.g., compound **42**) can be made by reaction with CO and the corresponding alcohol with Pd/C catalyst. The esters **J** may be further converted to other acyl derivatives by hydrolysis to the free acid, followed by activation to $-C(O)-Lv$, where Lv is a leaving group, by standard methods (e.g., March, *Advanced Organic Chemistry: Reactions, Mechanisms, and*
 15 *Structure*, 4th edition, August 1992, John Wiley & Sons, New York, ISBN 0471601802), and, for example, conversion to amides or other acyl derivatives by reactions generally known in the art. Alternatively, the esters **J** can be directly converted to amides by standard aminolysis reactions, e.g., by reaction with primary or secondary amines such as dimethylamine or pyrrolidine.

20 General Synthetic Scheme 2:

$R^{23} = COR^{24}$, ($R^{24} = H$, aryl, $(CH_2)_q$ aryl), $q = 1$ or 2 $R^{32} = H$, aryl, $(CH_2)_q$ aryl)

R^{29} = optionally substituted aryl, alkyl, alkenyl, alkynyl, cycloalkyl, heterocycloalkyl, or heteroaryl, or H.

In Scheme 2, intermediate **BB**, where R^{23} is CHO, (CO)aryl, or $CO(CH_2)_q$ aryl where q is 1 or 2, is transformed to tricyclic acyl hydrazone **H** by reaction with hydrazine.

General Synthetic Scheme 3:

10

In Scheme 3, the **M**, where L_v includes, for example, I, Br, or triflate, is coupled with a substituted alkyne **T** using palladium and copper catalysts (See e.g. Sonogashira, K., Tohda, Y., Hagihara, N. *Tetrahedron Lett.* 1975, 50, 4467-4470, incorporated herein by reference). The intermediate **N** can be cyclized with palladium catalyst (See e.g. Arcadi, A., Cacchu, S., Marinellito, F. *Tetrahedron Lett.* 1989, 30, 2581-2584, incorporated herein by reference) to give **P** which is further modified as described in Scheme 1 to the intermediate **BB**.

15

20

(d) Intermediate L - methyl 3-aminomethylindole-4-carboxylate hydrochloride:

Dry HCl gas was added to a solution of oxime intermediate K (2.4 g, 11 mmol) in 130 mL MeOH. Under an argon atmosphere, 0.2 g of 10% Pd/C was added. Using a three-way valve, the system was evacuated under vacuum. Hydrogen gas was introduced via a balloon, and the reaction mixture was vigorously stirred for 4 h. At this time the balloon was removed, and argon was reintroduced. The mixture was filtered and concentrated to give a solid which became violet in color. The solids were washed with Et₂O, protected from air and light, and placed under vacuum at room temperature. The violet solid (2.5 g, 96%) was used without further

A solution of Compound 21 (58 mg) in acetone (7.0 mL) was treated with 30% aqueous hydrogen peroxide (0.6 mL) at room temperature and the yellow solution was allowed to stir for three days. The acetone was removed in vacuo and the residue was taken-up in isopropyl alcohol. A solid was precipitated with the addition of an equal volume of cold hexanes and collected by a quick filtration.

Precautions were taken to prevent the solid from absorbing moisture from the atmosphere. The solid was recrystallized (isopropanol/acetone/CH₂Cl₂/hexanes) to give 2-(4-(N,N-dimethylamino)methylphenyl)-3,4,5,6-tetrahydro-1H-azepino[5,4,3-cd]indol-6-one, N-oxide, 37 mg (60%) as a pale yellow solid: ^1H NMR (300 MHz, d_6 -DMSO) 3.22 (s, 6H), 3.56 (br m, 4H), 4.63 (s, 2H), 7.40 (br t, 1H), 7.76 (br d, 1H), 7.87 (m, 5H), 8.29 (br t, 1H), 12.00 (br s, 1H). PARP Enzyme Inhibition Assay:

The PARP enzyme-inhibiting activities of the compounds of the invention were assayed as described by Simonin et al. (*J. Biol. Chem.* (1993), 268:8529-8535) and Marsischky et al. (*J. Biol. Chem.* (1995), 270:3247-3254) with minor modifications as follows. Samples (50 µL) containing 20 nM purified PARP protein, 10 µg/mL DNase I-activated calf thymus DNA (sigma), 500 µM NAD⁺, 0.5 µCi [³²P]NAD⁺, 2% DMSO, and various concentrations of test compounds were incubated in sample buffer (50 mM Tris pH 8.0, 10 mM MgCl₂, 1 mM tris(carboxyethyl)phosphine·HCl) at 25°C for 5 minutes. Under these conditions, the reaction rate was linear for times up to 10 minutes. The reaction was stopped by the addition of an equal volume of ice-cold 40% trichloroacetic acid to the samples,

which were then incubated on ice for 15 minutes. The samples were then transferred to a Bio-Dot microfiltration apparatus (BioRad), filtered through Whatman GF/C glass-fiber filter paper, washed 3 times with 150 μ L of wash buffer (5% trichloroacetic acid, 1% inorganic pyrophosphate), and dried. [32 P]ADP-Ribose incorporation into the acid-insoluble material was quantitated using a PhosphorImager (Molecular Dynamics) and ImageQuant software. Inhibition constants (K_i) were calculated by non-linear regression analyses using the velocity equation for competitive inhibition (Segel, *Enzyme Kinetics: Behavior and Analysis of Rapid Equilibrium and Steady-State Enzyme Systems*, John Wiley & Sons, Inc., New York (1975), 100-125). In the case of tight-binding inhibitors, 5 nM enzyme was used and the reaction was incubated at 25°C for 25 minutes. K_i values for tight-binding inhibitors were calculated using the equation described by Sculley et al. (*Biochim. Biophys. Acta* (1986), 874:44-53).

Cytotoxicity Potentiation Assay:

A549 cells (ATCC, Rockville, MD) were seeded into 96-well cell culture plates (Falcon brand, Fisher Scientific, Pittsburgh, PA) 16 to 24 hours before experimental manipulation. Cells were then treated with a test compound (or a combination of test compounds where indicated) for either 3 days or 5 days, at a concentration of 0.4 μ M. At the end of treatments, relative cell number was determined either by MTT assay or SRB assay. For the MTT assay, 0.2 μ g/ μ L of MTT (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide, Sigma Chemical Co., St. Louis, MO) was added to each well of a plate, and the plate was incubated in a cell-culture incubator for 4 hours. Metabolized MTT in each well was solubilized in 150 μ L of DMSO (Sigma Chemical Co.) with shaking and quantified with a Wallac 1420 Victor plate reader (EG&G Wallac, Gaithersburg, MD) at 540 nm. For the SRB assay, cells were fixed with 10% trichloroacetic acid (Sigma Chemical Co) for an hour at 4°C. After extensively washing, fixed cells were stained for 30 minutes with 0.4% sulforhodamine B (SRB, Sigma Chemical Co.) in 1% acetic acid (Sigma Chemical Co). Unbound SRB was washed away with 1% acetic acid.

Then the cultures were air-dried, and bound dye was solubilized with 10 mM

unbuffered Tris base (Sigma Chemical Co) with shaking. The bound dye was measured photometrically with the Wallac Victor plate reader at 515 nm. The ratio of the OD (optical density) value of a compound-treated culture to the OD value of a mock-treated culture, expressed in percentage, was used to quantify the cytotoxicity of a compound. The concentration at which a compound causes 50% cytotoxicity is referred to as IC_{50} . To quantify the potentiation of the cytotoxicity of topotecan or temozolomide by test compounds, a dimensionless parameter PF_{50} is used and is defined as the ratio of the IC_{50} of topotecan or temozolomide alone to the IC_{50} of topotecan or temozolomide in combination with a test compound. For the compounds of the invention, PF_{50} values were determined by testing with topotecan.

Inhibition constants (K_i values) and cytotoxicity potentiation parameters (PF_{50} values) as determined for exemplary compounds of the invention are presented in Table 1 below. If there are two K_i values for a single compound, it means that the compound K_i was tested twice.
